Parallel Computing

Lecture 17: GPUs - Intro

Mohamed Zahran (aka Z)
mzahran@cs.nyu.edu
<http://www.mzahran.com>

Two Main Goals for Current Architectures

- Maintain execution speed of old sequential programs
- Increase **throughput** of parallel programs

Two Main Goals for Current Architectures

- Maintain execution speed of old sequential programs

→ CPU

- Increase throughput of parallel programs

→ GPU

Performance

Source: NVIDIA CUDA C Programming Guide

CPU is optimized for sequential code performance

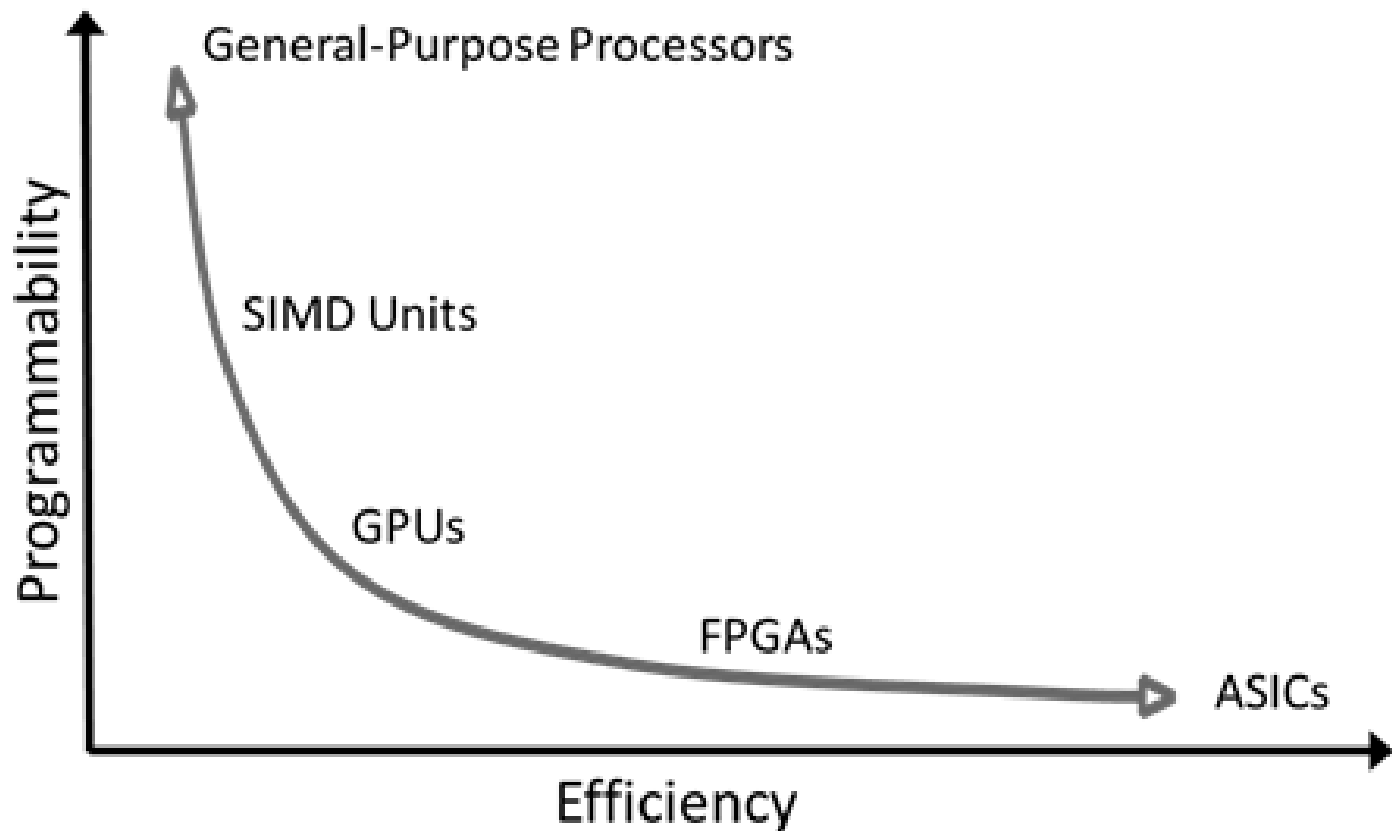

Almost 10x the bandwidth of multicore (relaxed memory model)

Memory Bandwidth

Source: NVIDIA CUDA C Programming Guide

Where do GPU stand among other chips?

What are GPUs good for?

Regularity + Massive Parallelism

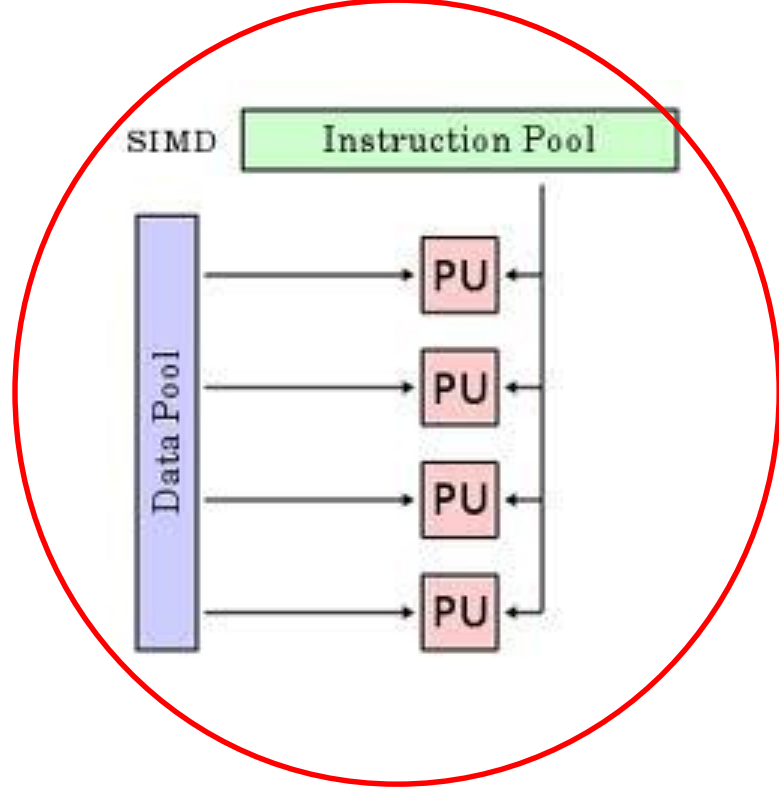

Is Any Application Suitable for GPU?

- Heck no!
- You will get the best performance from GPU if your application is:
 - Computation intensive
 - Many **independent** computations
 - Many **similar** computations

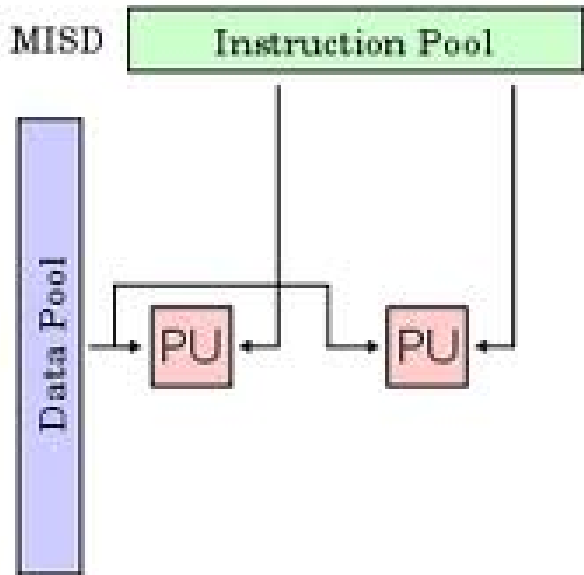

Let's Remember Flynn Classification

- A taxonomy of computer architecture
- Proposed by Micheal Flynn in 1966
- It is based two things:
 - Instructions
 - Data

	Single instruction	Multiple instruction
Single data	SISD	MISD
Multiple data	SIMD	MIMD

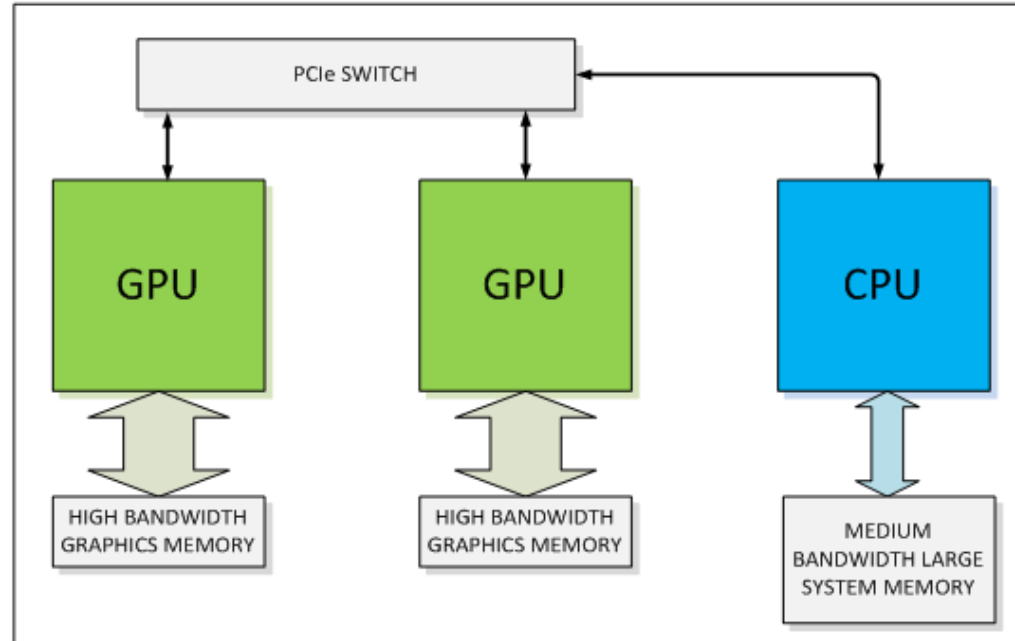

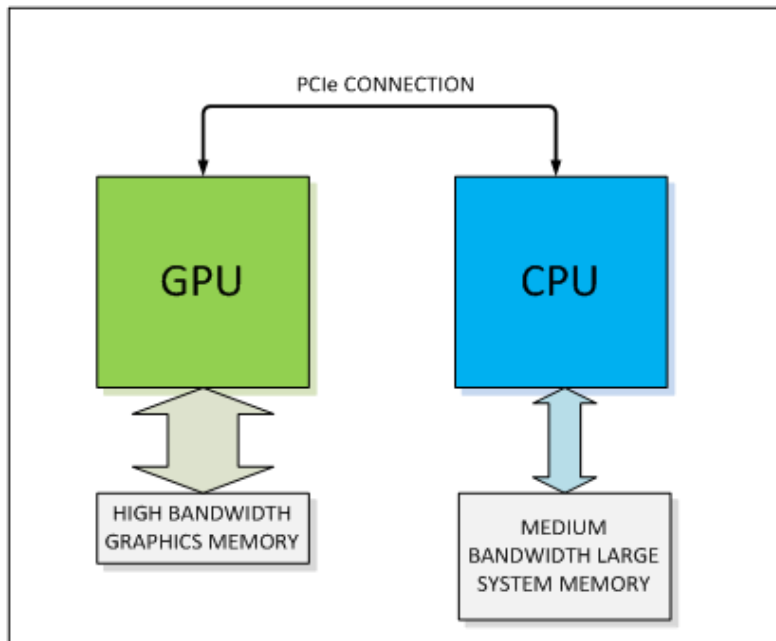

PU = Processing Unit

Problems Faced by GPUs

- Need enough parallelism
- Under-utilization
- Bandwidth to CPU

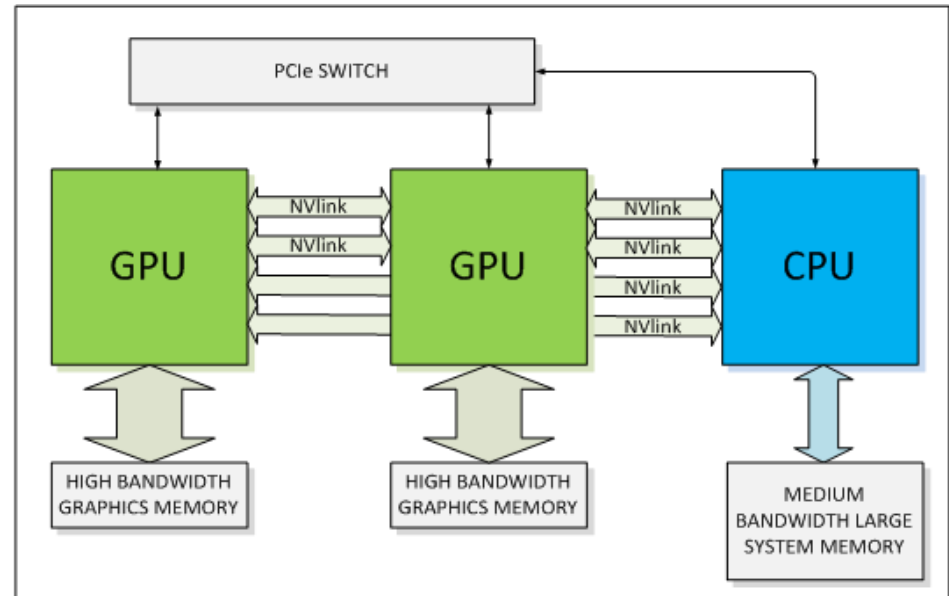

Let's Take A Closer Look:
The Hardware

- PCIe 3.0 speeds ~32 GB-transfers per second per lane
- PCIe 4.0 is about the double of version 3.0
- widest supported links = 16 lanes
- Recently: NVLINK

With the new NVLink

Bandwidth of ~80GB/s per link

Modern GPU Hardware

- GPUs have many parallel execution units and higher transistor counts, while CPUs have few execution units and higher clock speeds
- GPUs have much deeper pipelines.
- GPUs have significantly faster and more advanced memory interfaces as they need to shift around a lot more data than CPUs

Single-Chip GPU vs Supercomputers

(Next range is exaops)

A Modern GPUs

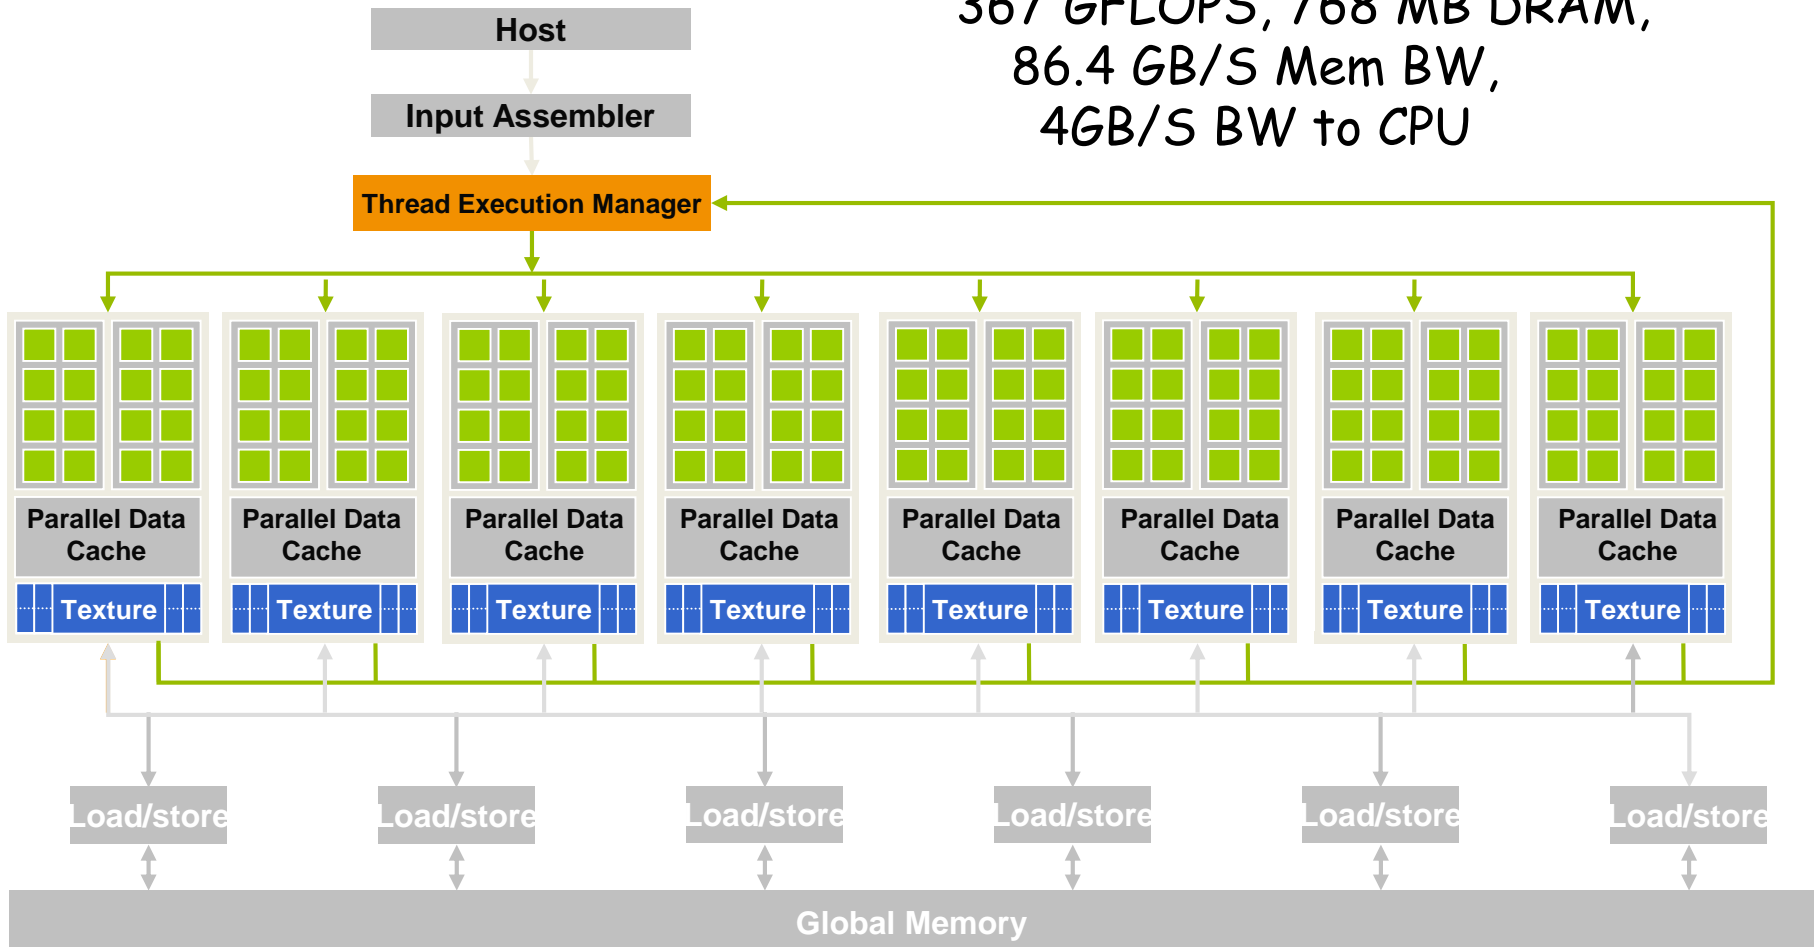

x124

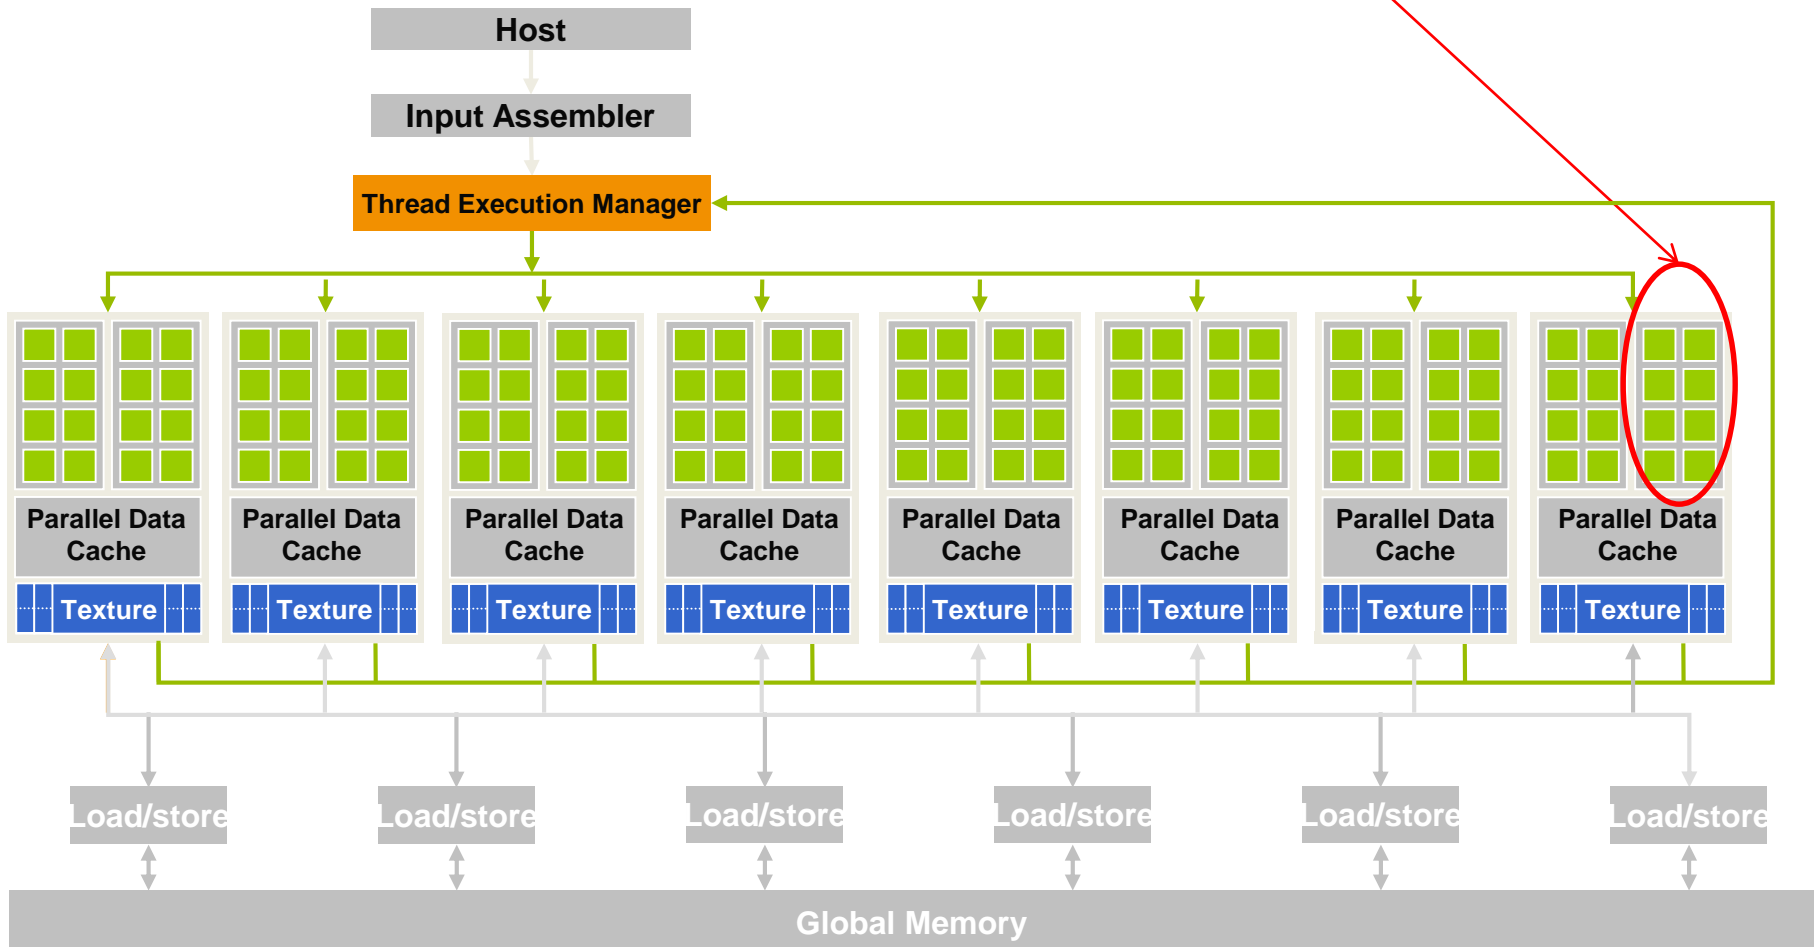

A Glimpse at At A GPGPU: GeForce 8800 (2007)

16 highly threaded SM's, >128 FPU's,
367 GFLOPS, 768 MB DRAM,
86.4 GB/S Mem BW,
4GB/S BW to CPU

A Glimpse at A Modern GPU

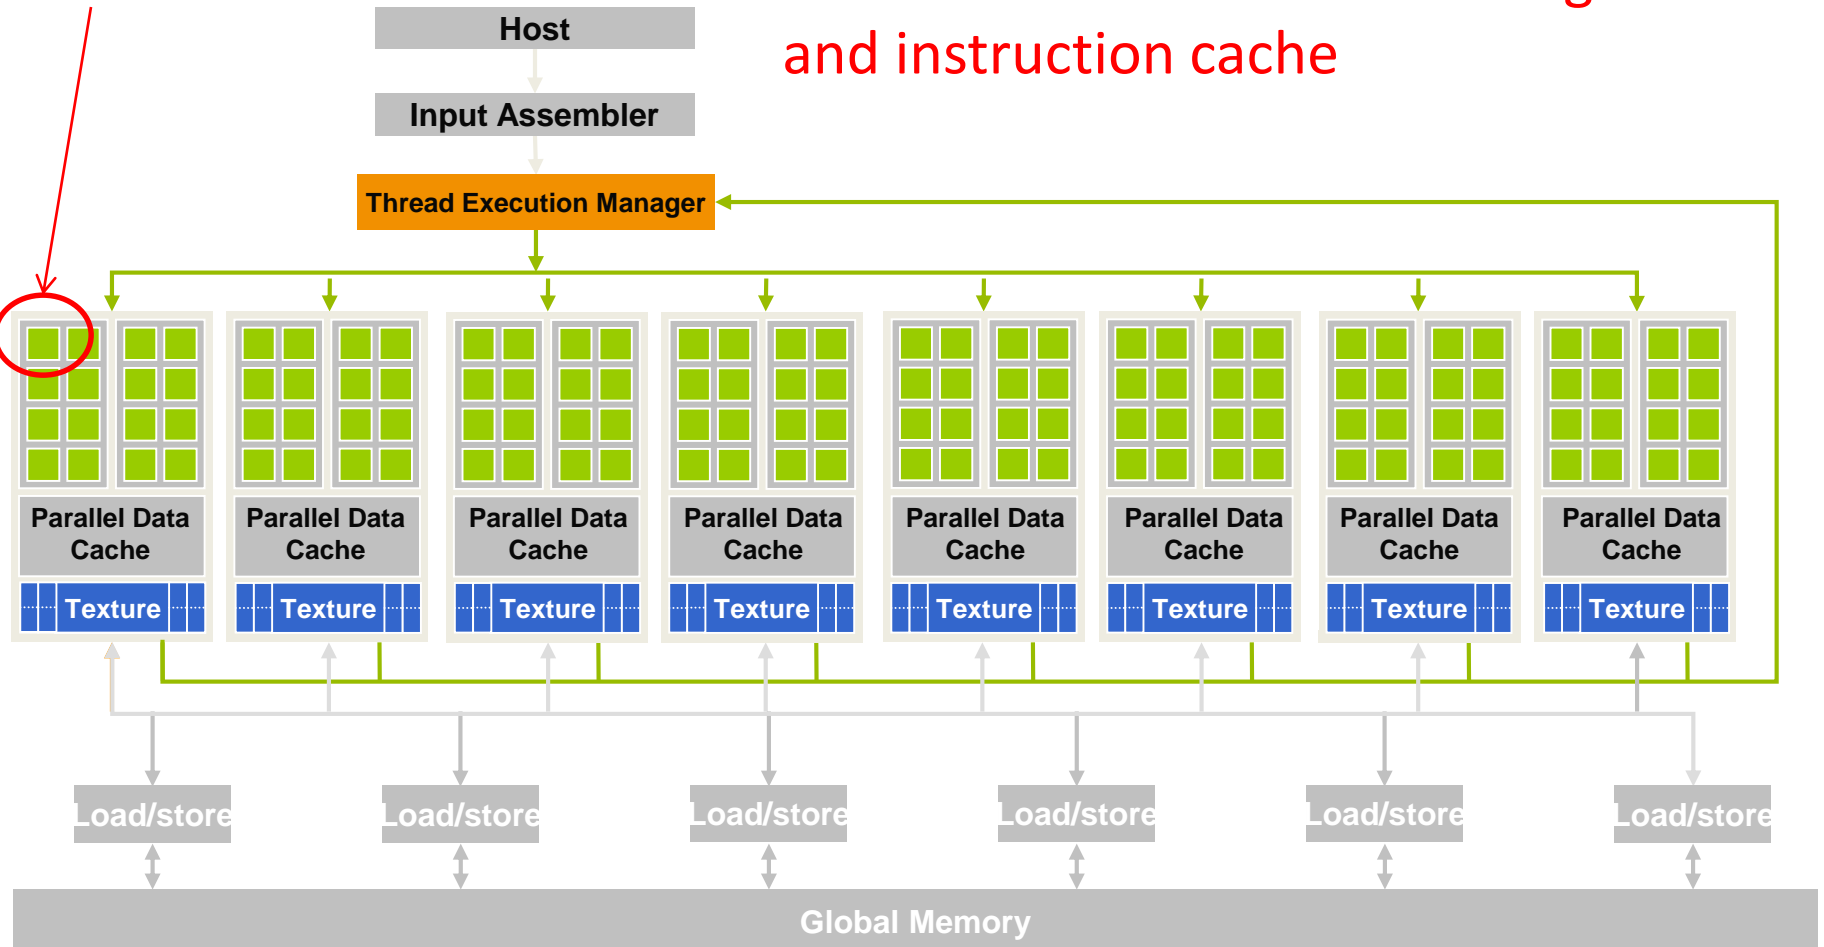

Streaming Multiprocessor (SM)

A Glimpse at A Modern GPU

Streaming Processor (SP)

SPs within SM share control logic and instruction cache

Scalar vs Threaded

Scalar program (i.e. sequential)

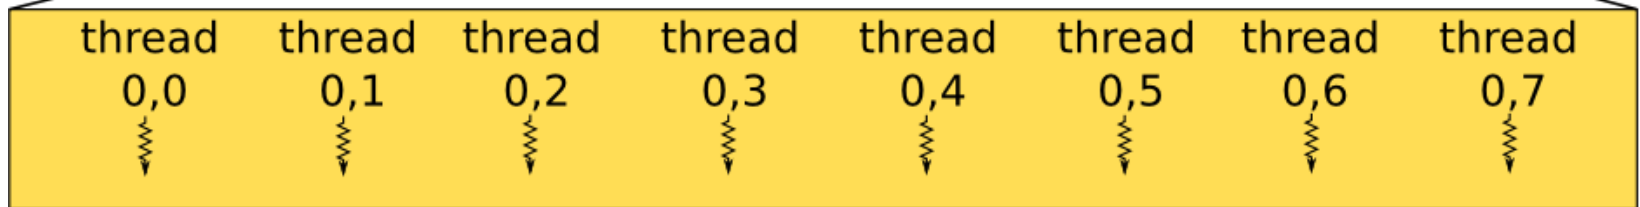

```
float A[4][8];  
  
for(int i=0;i<4;i++){  
    for(int j=0;j<8;j++){  
        A[i][j]++;  
    }  
}
```

Multithreaded: (4x1)blocks – (8x1) threads

Grid kernel contains 4 x 1 thread blocks

Thread Block

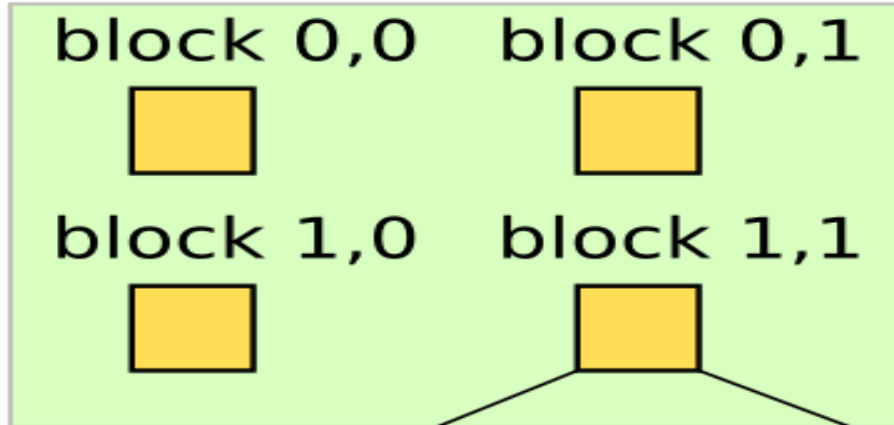

Each thread block contains 8 x 1 threads

Thread ⚡

Multithreaded: (2x2)blocks – (4x2) threads

Grid

kernel contains 2 x 2 thread blocks

Thread ⚡

Thread Block

Each thread block contains 4 x 2 threads

Scheduling Thread Blocks on SM

Grid

kernelF contains 2 x 2 thread blocks

Example:

Scheduling 4 thread blocks on 3 SMs.

Thread ↓

Thread Block

Each thread block contains 4 x 2 threads

Another NVIDIA GPU: FERMI

32 cores/SM

~3B Transistors

Another NVIDIA GPU: Kepler

~7.1B transistors
192 cores per SMX

Nvidia Chip GK110 Based on Kepler Architecture

- 7.1 billion transistors
- More than 1 TFlop of double precision throughput
 - 3x performance per watt of Fermi
- New capabilities:
 - Dynamic parallelism
 - Hyper-Q (several cores using the same GPU)
 - Nvidia GPUDirect

Another NVIDIA GPU: Maxwell

~8B transistors
128 cores per SMM
(Nvidia claims a **128**
CUDA core SMM
has **90%** of the
performance of
a **192** CUDA core SMX.)

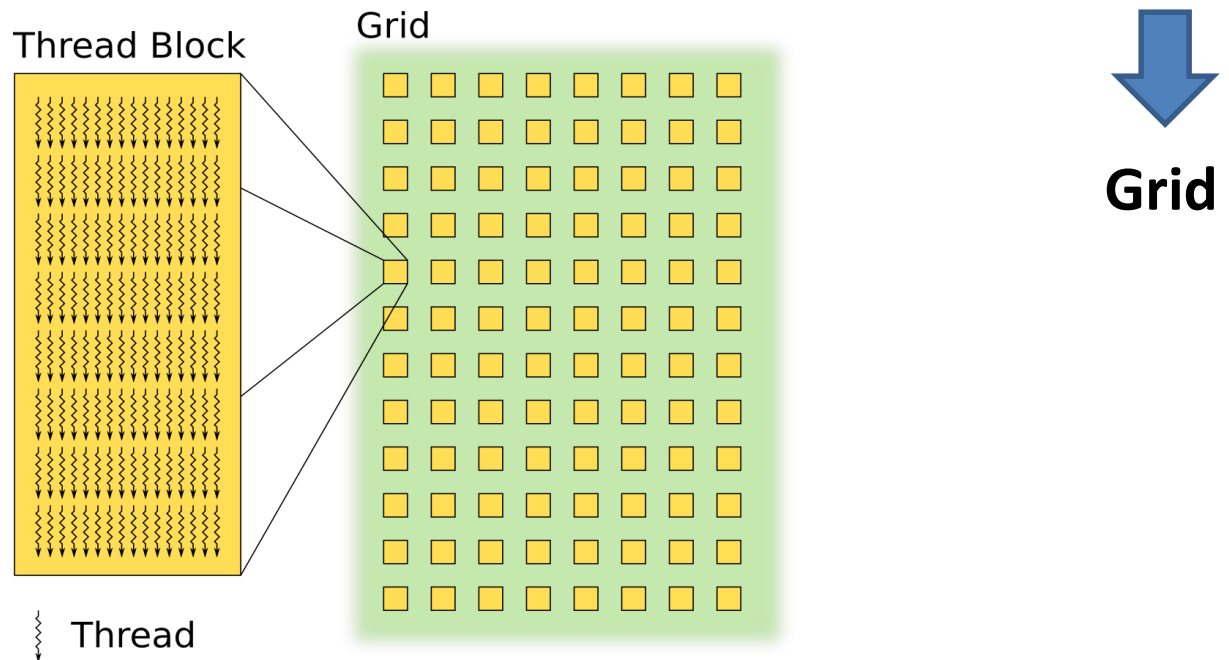

Main Goals of Newer GPUs

- Increasing floating-point throughput
- Allowing software developers to focus on algorithm design rather than the details of how to map the algorithm to the hardware
- Power efficiency

Quick Glimpse At Programming Models

Application → Kernels → Threads → Blocks

Quick Glimpse At Programming Models

- **Application** can include multiple **kernels**
- **Threads** of the same **block** run on the same SM
 - So threads in SM can operate and share memory
 - Block in an SM is divided into **warps** of 32 threads each
 - A warp is the fundamental unit of dispatch in an SM
- Blocks in a **grid** can coordinate using global shared memory
- Each grid executes a kernel

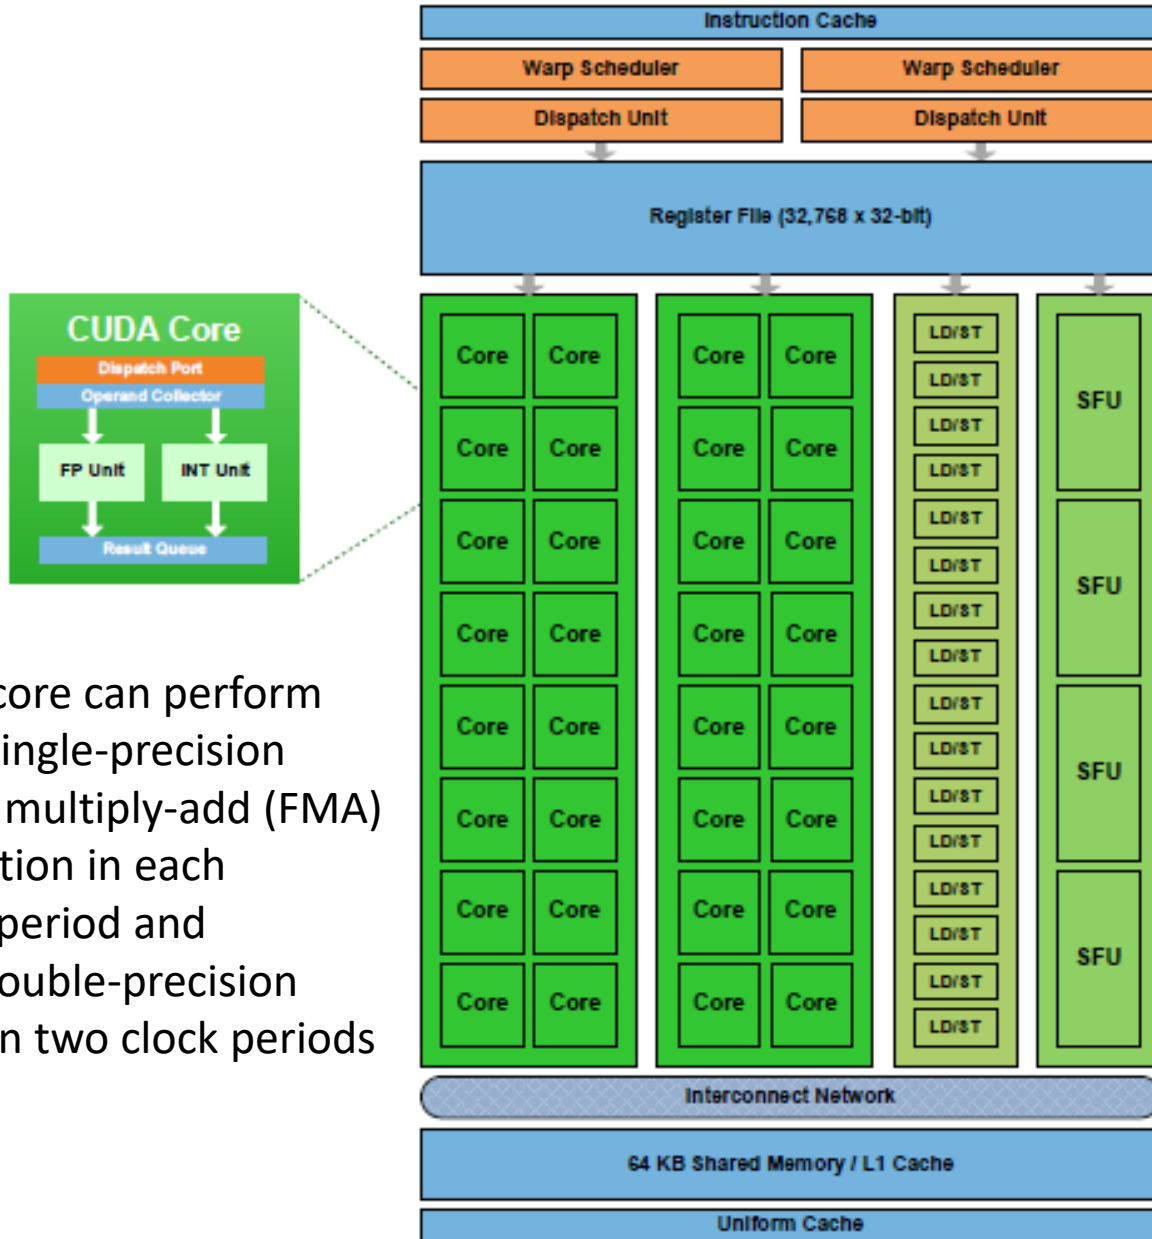

Scheduling In NVIDIA GPUs

- At any point of time the entire **device** is dedicated to a **single application**
 - Switch from an application to another takes ~25 microseconds
- Modern GPUs can simultaneously execute **multiple kernels of the same application**
- Two **warps** from different blocks (or even different kernels) can be issued and executed simultaneously
- More advanced GPUs can do more than that but we will concentrate on the above only here.

Scheduling In NVIDIA GPUS

- Two-level, distributed thread scheduler
 - At the chip level: a global work distribution engine schedules thread blocks to various SMs
 - At the SM level, each warp scheduler distributes warps of 32 threads to its execution units.

An SM in Fermi

- 32 cores
- SFU = Special Function Unit
- 64KB of SRAM split between cache and local mem

Each core can perform one single-precision fused multiply-add (FMA) operation in each clock period and one double-precision FMA in two clock periods

The Memory Hierarchy

- All addresses in the GPU are allocated from a continuous 40-bit (one terabyte) address space.
- **Global**, **shared**, and **local** addresses are defined as ranges within this address space and can be accessed by common load/store instructions.
- The load/store instructions support 64-bit addresses to allow for future growth.

The Memory Hierarchy

- Local memory in each SM
- The ability to use some of this local memory as a first-level (L1) cache for global memory references.
- Beside L1, each SM has also shared memory.
- Because the access latency to this memory is also completely predictable, algorithms can be written to interleave loads, calculations, and stores with maximum efficiency.
- Modern GPUs are also equipped with an L2 cache, shared among all SMs.

Fermi Memory Hierarchy

GPUs Today

- Are more and more general purpose and not only for graphics
- Discrete
 - separate chip on-board like all Nvidia GPUs and AMD GPUs
- Integrated
 - With the CPU on the same chip like the GPU in Intel Sandy Bridge and Ivy Bridge

Memory Bus

- Memory bus
 - Path between GPU itself and the video card memory
 - **Bus width** and **speed of memory** → bandwidth (GB/s) → more is better
 - Example:
 - GTX 680: 6GHz memory and 256-bit interface → 192.2 GB/s
 - GTX Titan: 6GHz memory and 384-bit interface → 288.4 GB/s
 - Since most modern GPUs use 6GHz memory, the bus width is the one that makes the difference.

Conclusions

- The main keywords:
 - data parallelism
 - kernel, grid, block, and thread
 - warp
- Some applications are better run on CPU while others on GPU
- Main limitations
 - The parallelizable portion of the code
 - The communication overhead between CPU and GPU
 - Memory bandwidth saturation
